
HEAT FLUXES & STRESS FROM TURBULENCE AND COARE 3.x

R/V Mirai, MR14-05, Dutch Harbor AK to Yokohama, Japan, Aug 31 - Oct 10, 2014

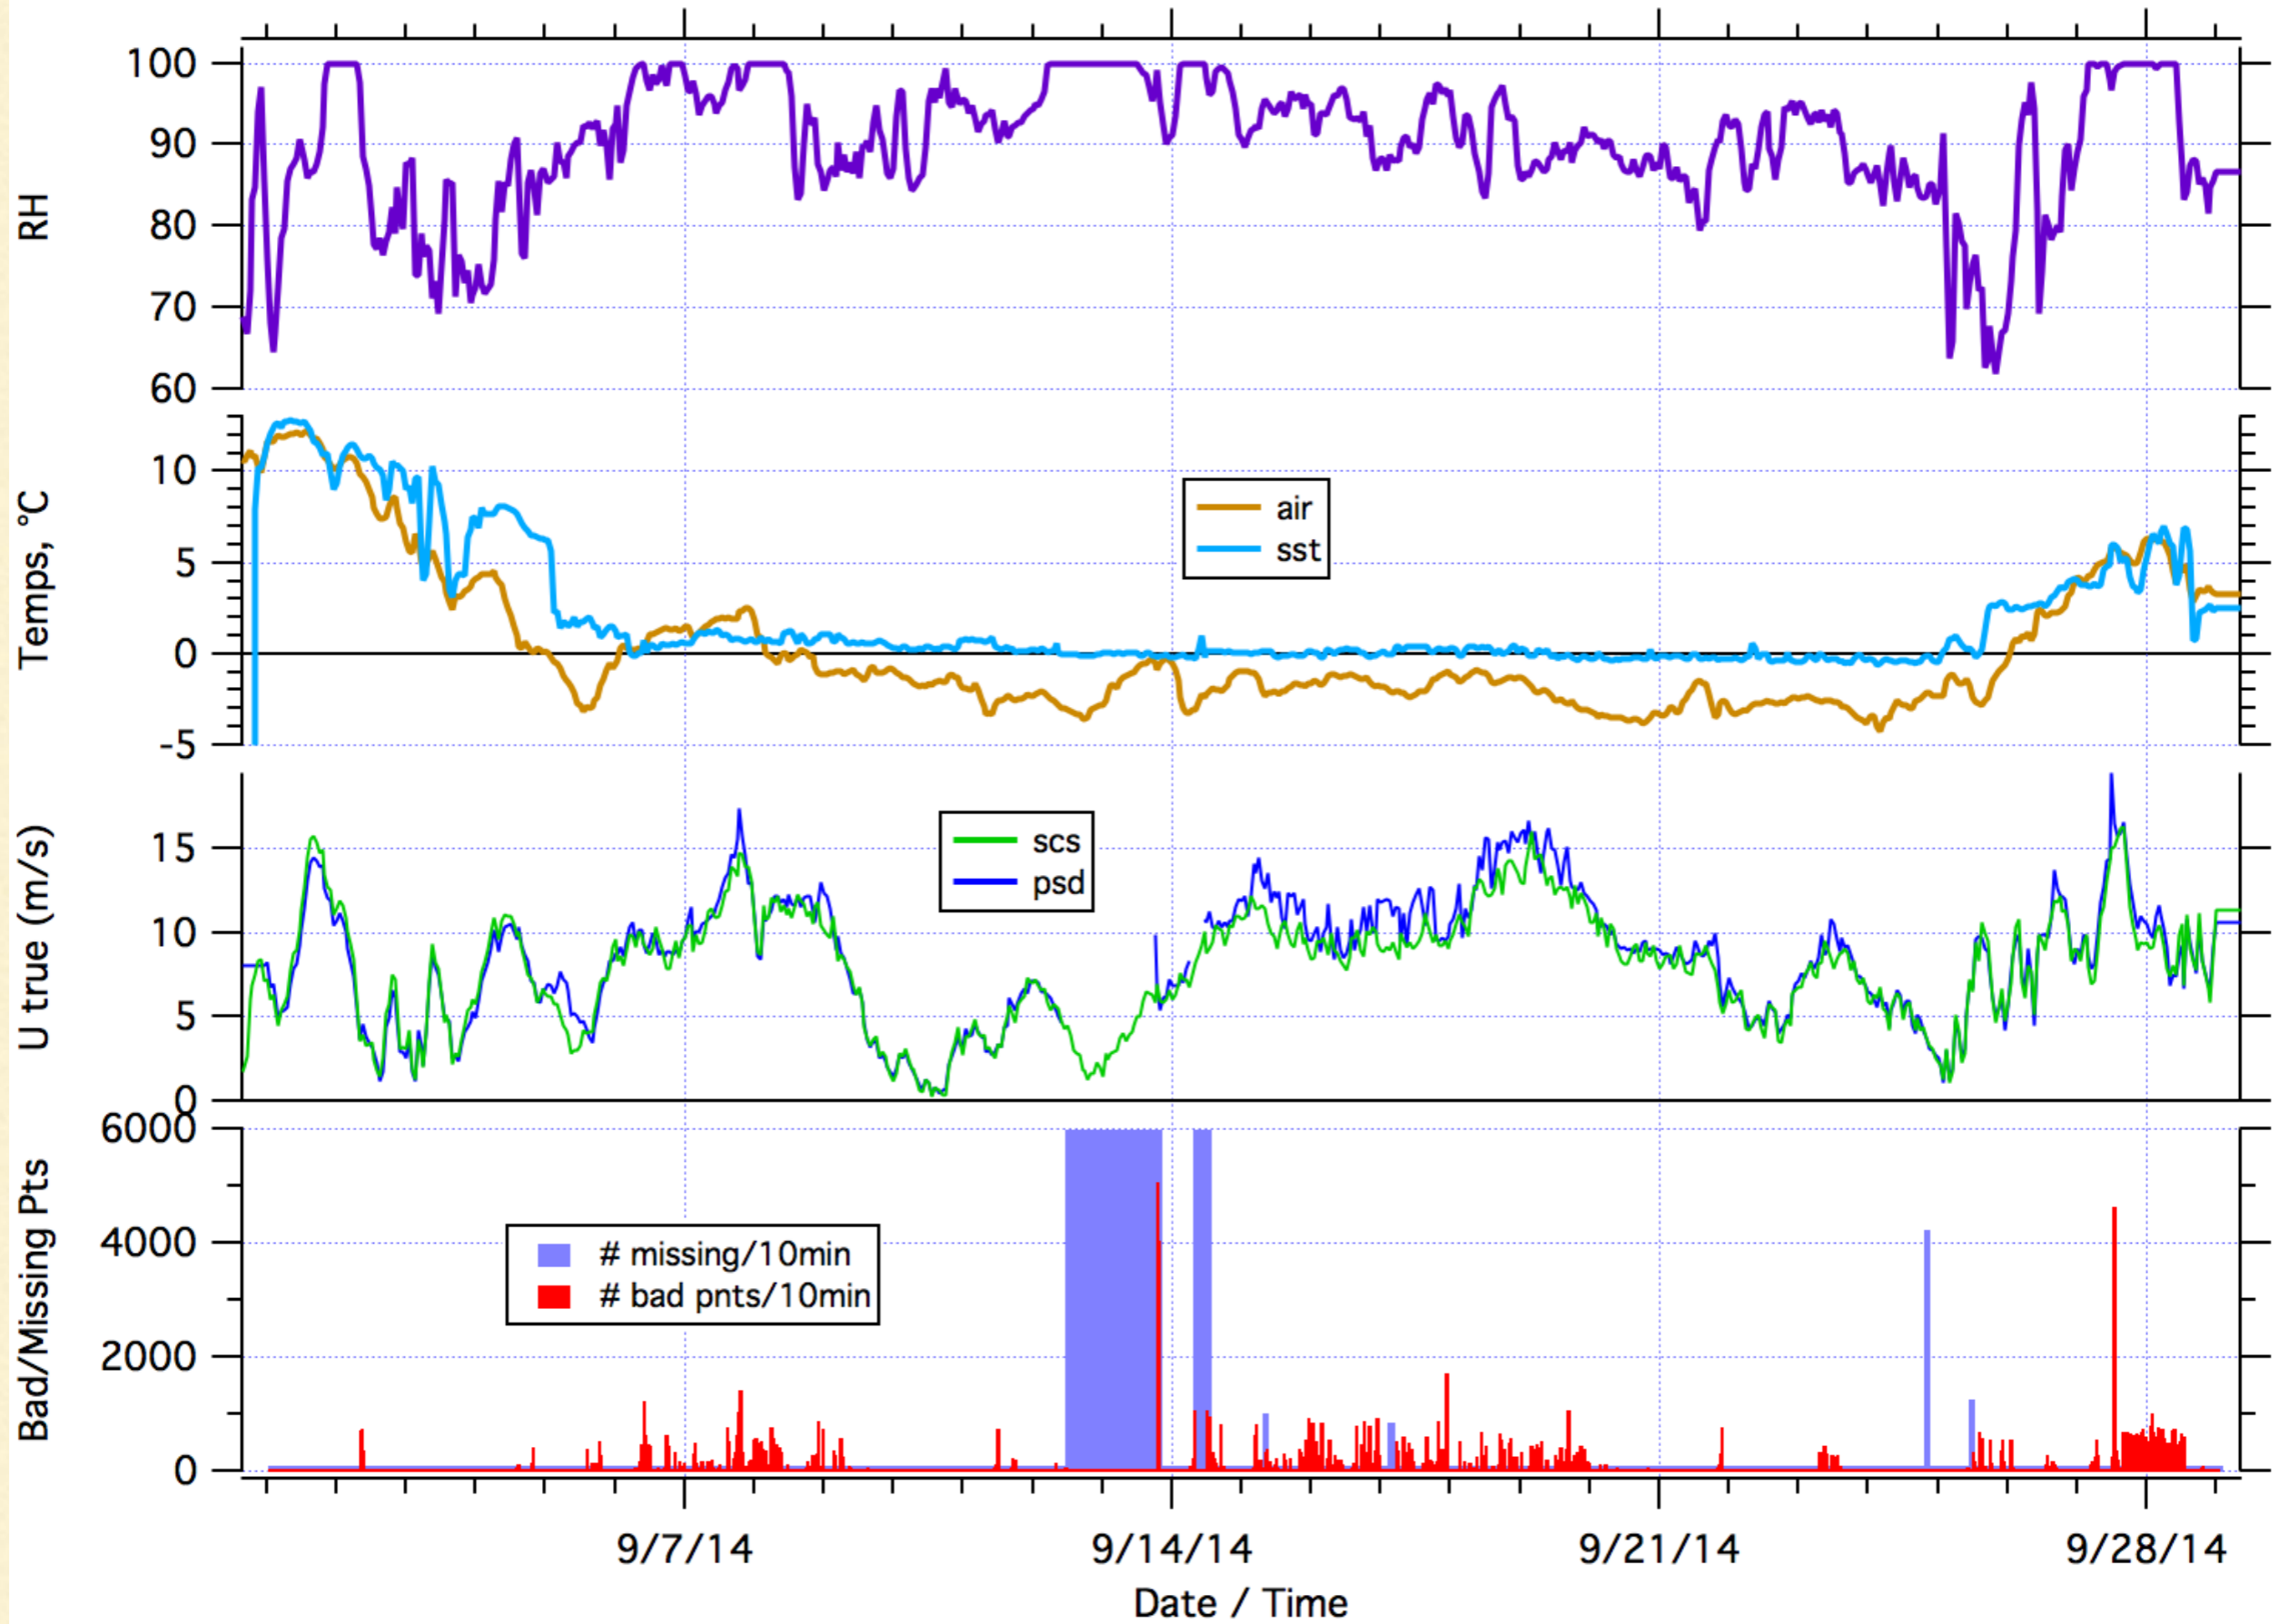

Byron Blomquist (Univ. Colorado, CIRES & NOAA/ESRL/PSD3, Climate and Weather Physics)

MEASUREMENTS & PRODUCTS

- Bulk meteorological observations: T, P, RH, Wind, PSP, PIR.
 - Turbulent variables: Wind (U,V,W) and water vapor, 10 Hz.
 - Flux measurements: Stress , Sensible Heat, Latent Heat by two methods: eddy correlation and inertial dissipation.
 - Bulk Model: Stress, Sensible Heat, Latent Heat, L, Rain Heat Flux, and many other related quantities.
-

BULK MET MEASUREMENTS

- In most cases PSD and ship met measurements compare very well.
 - Ship measurements are used for COARE model, with adjustments for PIR temperature correction, icing conditions and (possibly) PSP calibration and offset.
 - PSD sonic anemometer affected by frost and rain: illustrated in next slide.
-

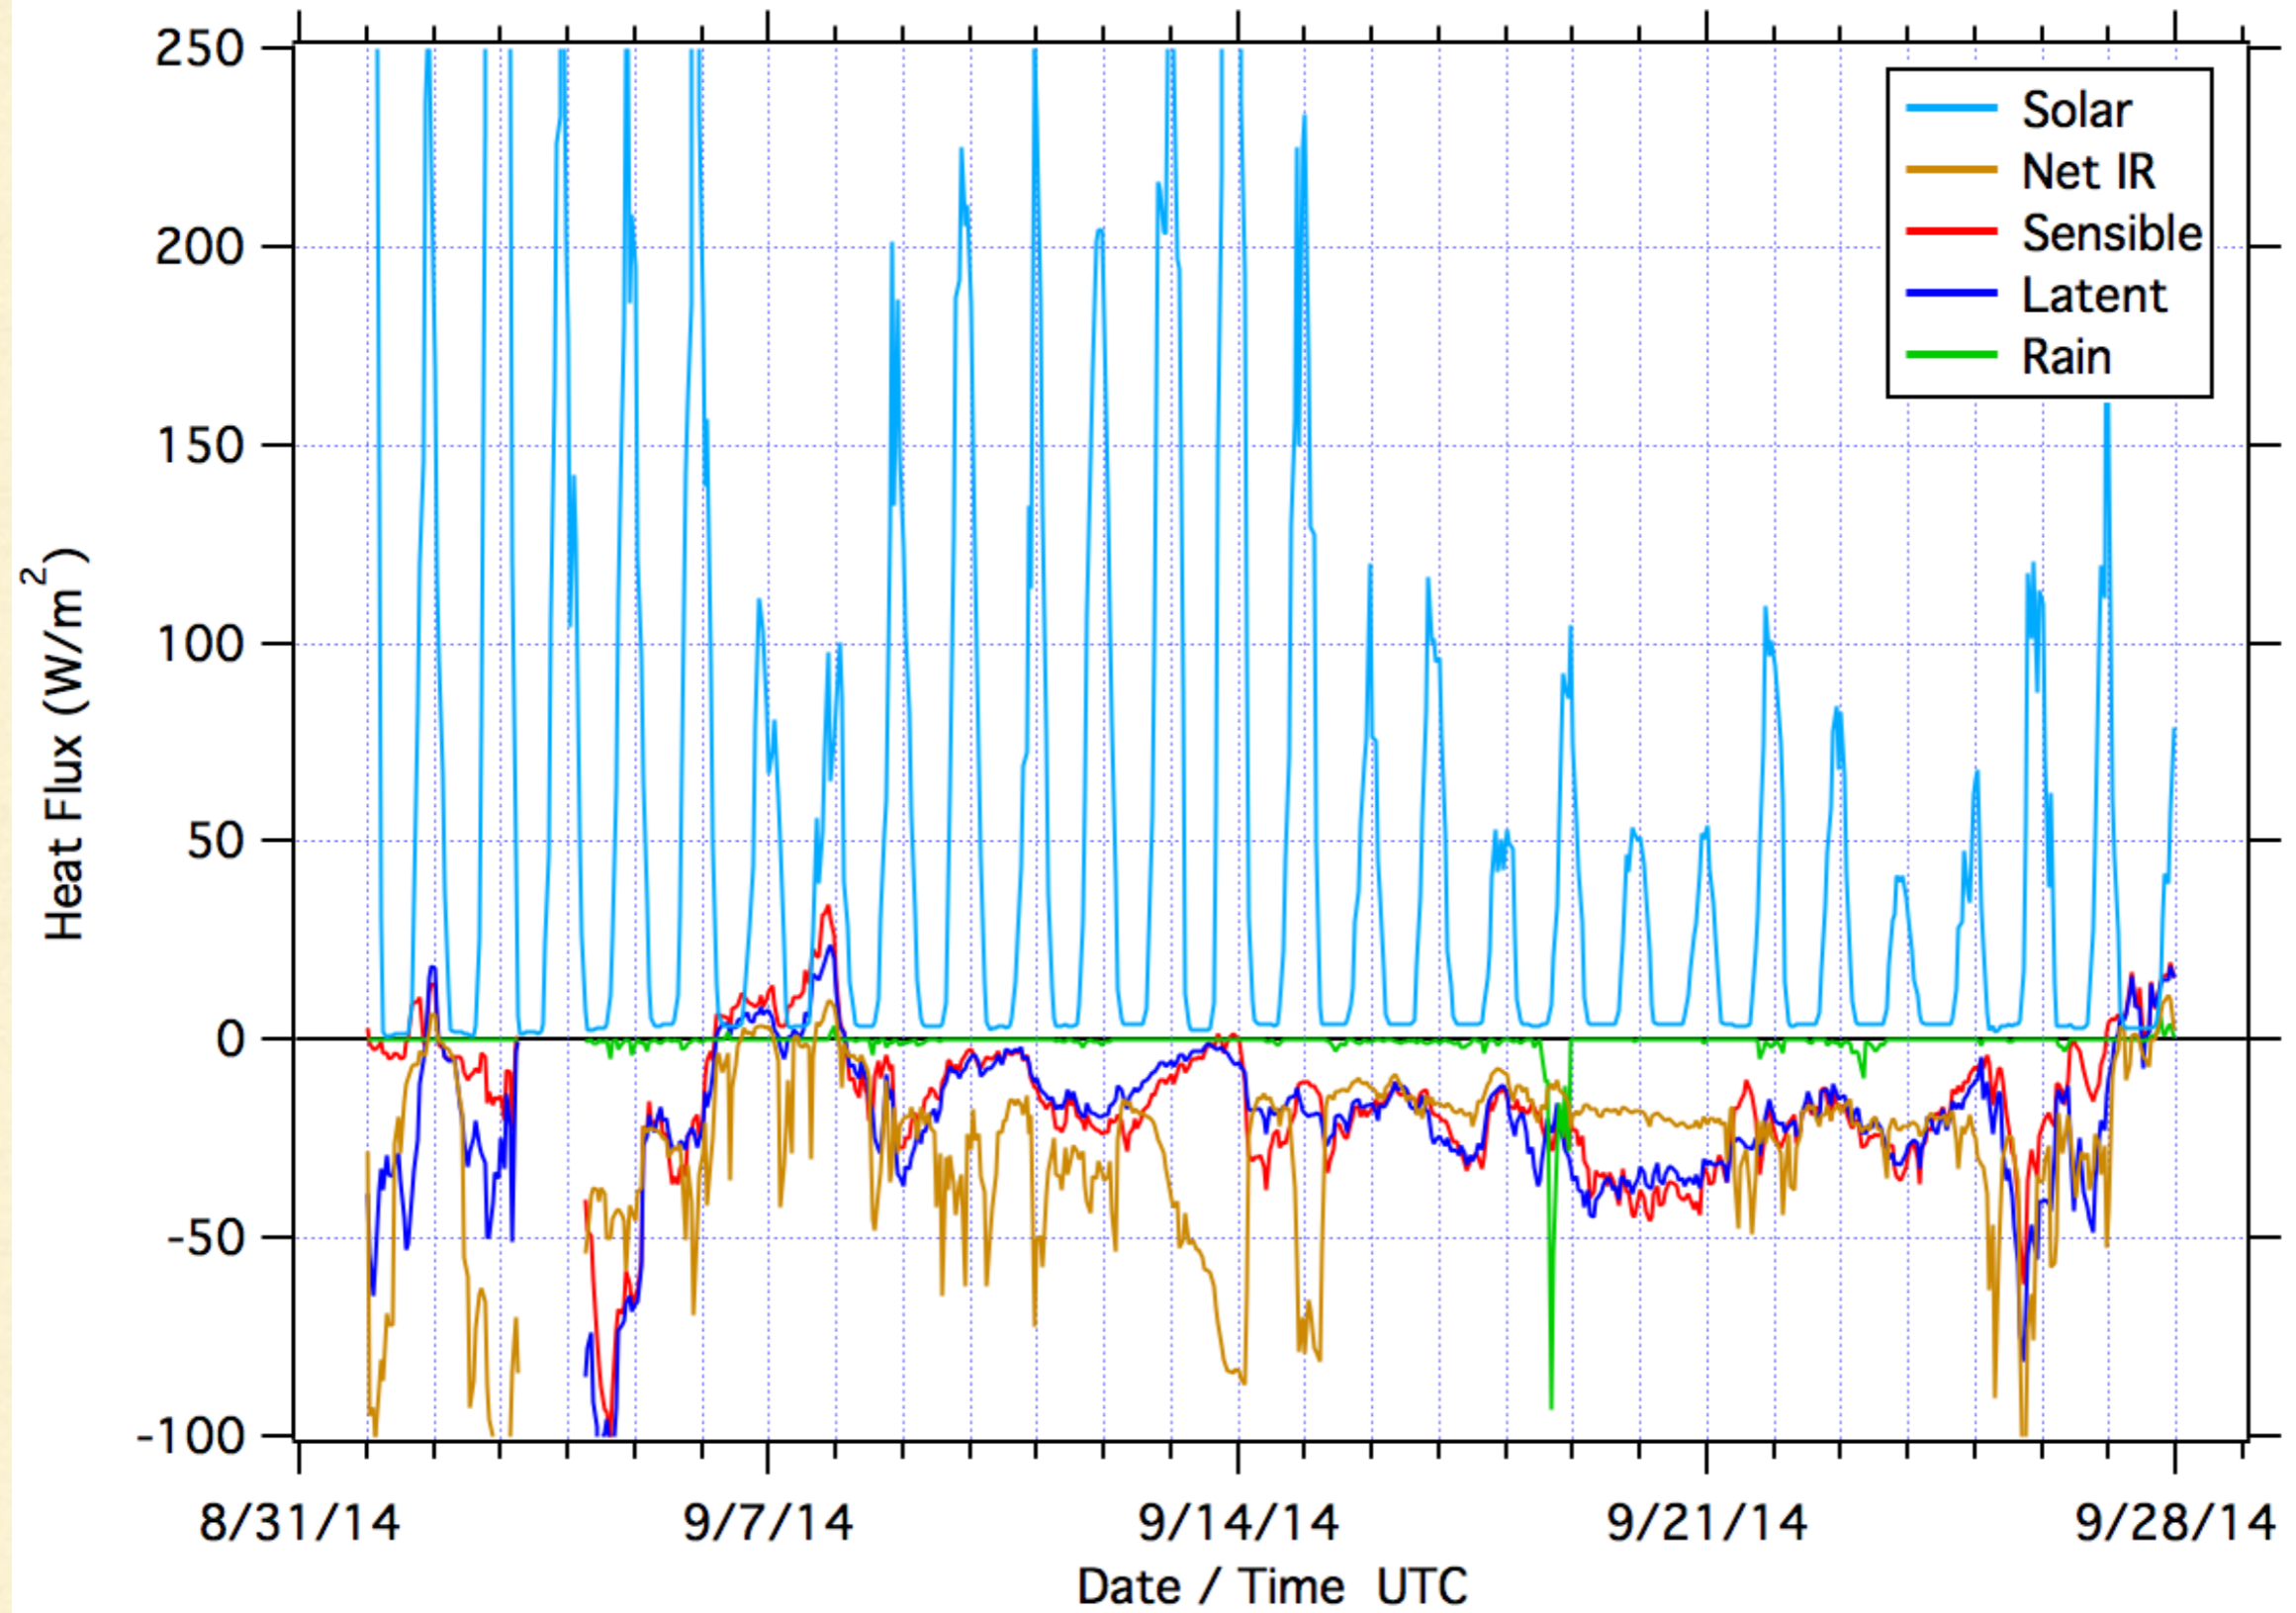

HEAT FLUXES

- Sensible Heat: best value is avg of covariance and inertial dissipation results.
- Latent Heat: best value is from inertial dissipation due to issues with the sonic anemometer and Licor in cold, wet condition

$$H_n(sea) = 0.955 R_s - R_{l,net} - H_s - H_l - H_{rain}$$

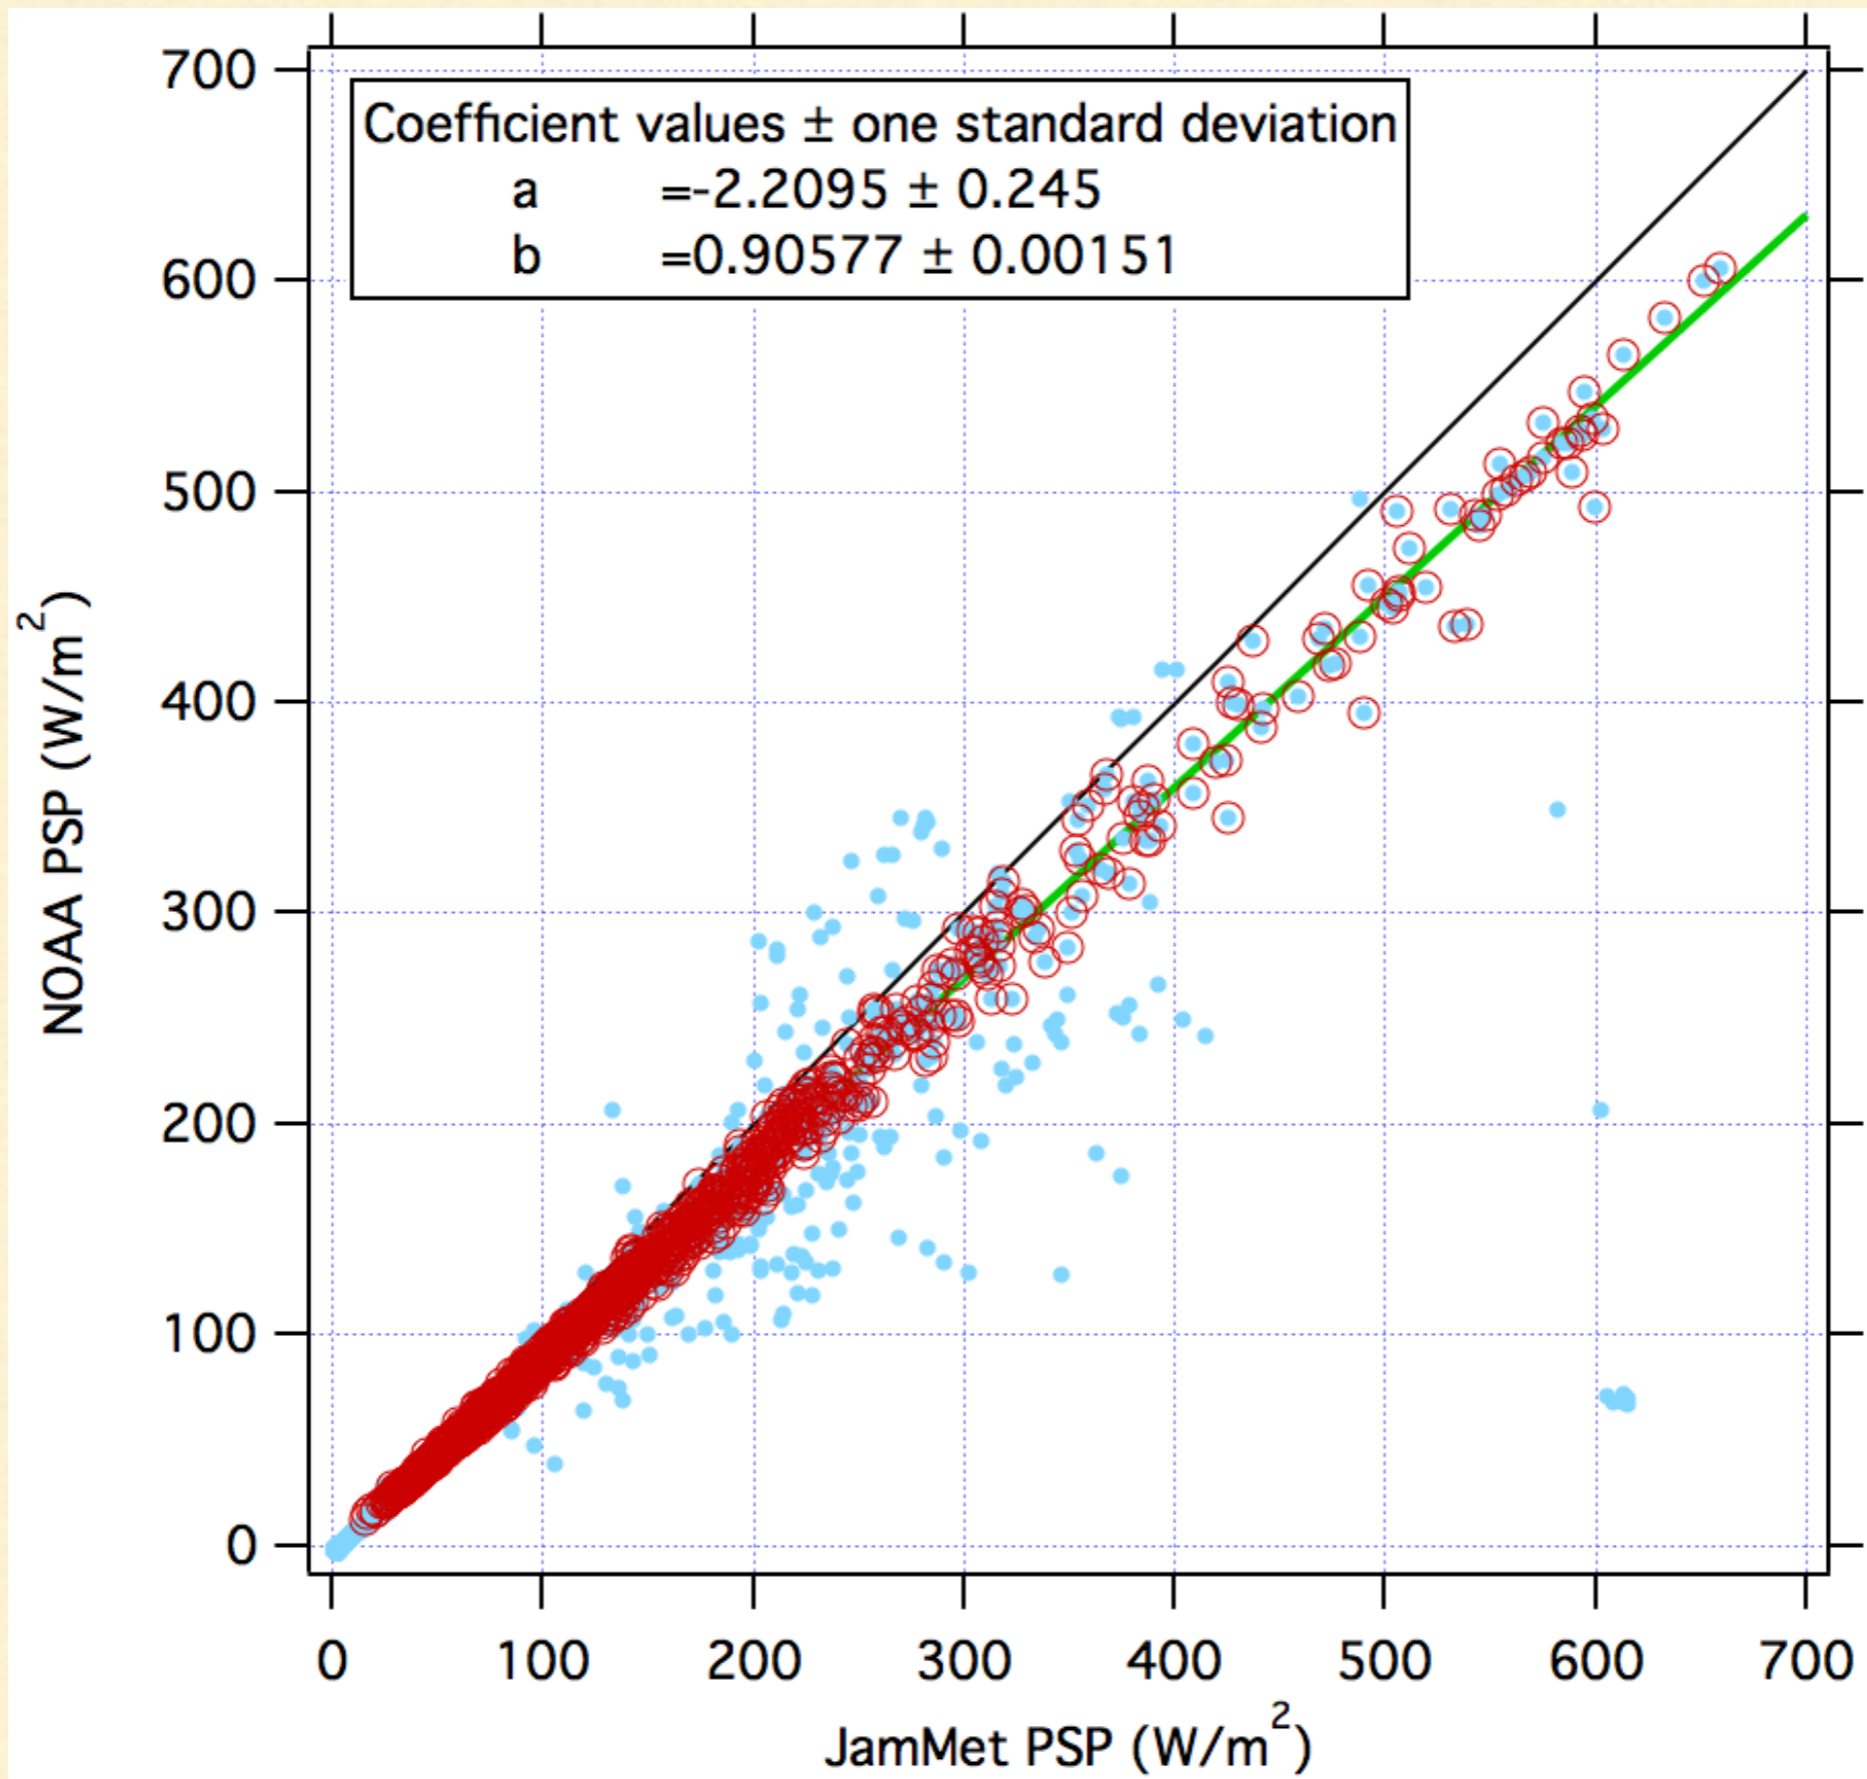

$$nR_l = 0.97(S_b T_{s,K}^4 - R_l)$$
